For hundreds of years Fermat’s Last Theorem, which stated simply that for $n > 2$ there exist no integers $a, b, c > 1$ such that $a^n = b^n + c^n$, has remained elusively unproven. (A recent proof is believed to be correct, though it is still undergoing scrutiny.) It is possible, however, to find integers greater than 1 that satisfy the “perfect cube” equation $a^3 = b^3 + c^3 + d^3$ (e.g. a quick calculation will show that the equation $12^3 = 6^3 + 8^3 + 10^3$ is indeed true). This problem requires that you write a program to find all sets of numbers $\{a, b, c, d\}$ which satisfy this equation for $a \leq 200$.

**Output**

The output should be listed as shown below, one perfect cube per line, in non-decreasing order of $a$ (i.e. the lines should be sorted by their $a$ values). The values of $b$, $c$, and $d$ should also be listed in non-decreasing order on the line itself. There do exist several values of $a$ which can be produced from multiple distinct sets of $b$, $c$, and $d$ triples. In these cases, the triples with the smaller $b$ values should be listed first.

The first part of the output is shown here:

Cube = 6, Triple = (3,4,5)
Cube = 12, Triple = (6,8,10)
Cube = 18, Triple = (2,12,16)
Cube = 18, Triple = (9,12,15)
Cube = 19, Triple = (3,10,18)
Cube = 20, Triple = (7,14,17)
Cube = 24, Triple = (12,16,20)
